

Hands On Lab!

30 minutes

HCL: HashiCorp Configuration Language

- Play with variable file provided (main.tf)
- Use **terraform init** to initialize the project
- To test the code just run:

terraform plan

terraform apply

- The instructions are on the next slide

HCL: HashiCorp Configuration Language

- Output the **application_name** with only the 3 first characters
- Output the **letters** array in **one single string** with **dashes** to separate each letter
- Create a variable **string** called **domain** and when you output it make sure it's **lowercase**
- Return the **node count** in a dedicated output
- Return the **node size** in a dedicated output
- Output a resource group name which will be a **concatenation** of the official abbreviation "rg" and the **application name** and **domain** formatted previously. Dashes must separate each part.
E.g. rg-<application name>-<domain>
